Quantitative metrics for the selection of physiological modes of action of Flupyradifurone and 2,4-D in *Discoglossus galganoi* larvae

Supporting Information for "Predictive modelling of chemical mixture toxicity to amphibians in *Discoglossus galganoi* larvae and metamorphs"

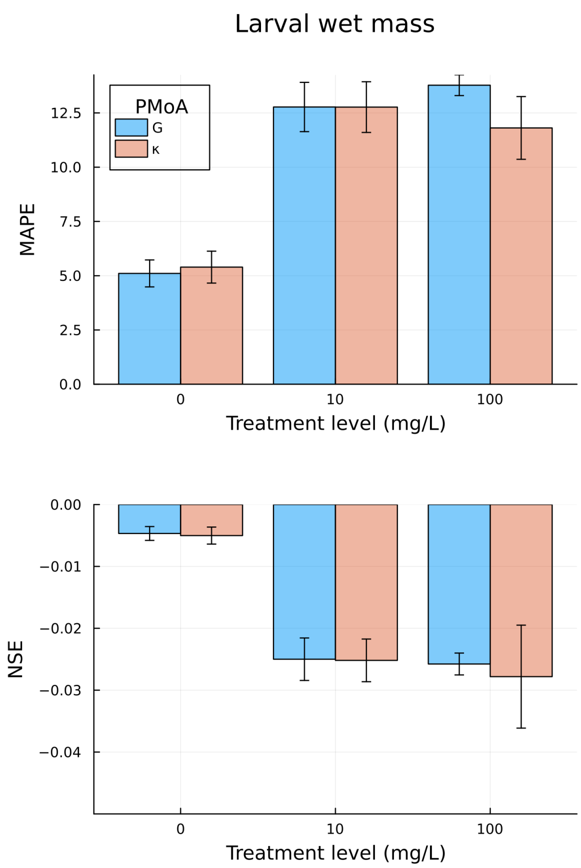
Bootstrapping procedure

The mean absolute percentage error (MAPE) and Nash-Sutcliffe-Efficiency (NSE) were calculated for each fitted or predicted response and each test concentration.

A bootstrapping procedure was implemented that yields the confidence intervals of MAPE and NSE, resulting from variability in model output due to the simulated individual variability. In each case, we performed 2,000 bootstrap resamplings (n = 100 per bootstrap sample) from 100 simulation runs and calculated MAPE and NSE for each bootstrap sample. We then calculated the confidence intervals as the 5th and 95th percentile of MAPE and NSE values across bootstrap samples.

2,4-D

Flupyradifurone



(a) flpcalibwetmass

Figure 1: Quantitative metrics for each tested PMoA of Flupyradifurone in the calibration data. Error bars indicate 5 - 95% credible intervals, obtained from 2,000 bootstrap samples
